Dear Dr. Jaffe:

Thank you for your recent letter of May 20, 1969, inquiring about a calculated estimate of the mean residence time based on your figure of CO production and our data on C¹ content of atmospheric CO.

Actually, given the concentration of CO and its rate of production we can calculate its mean life without recourse to the C^{14} specific activity. If we assume the CO concentration to be 0.1 ppm this means there is 0.1 mg CO/cm² of the earth surface. Your estimate of the rate of production of CO, 2 x 10^8 tons/year, works out to $\frac{2 \times 10}{5 \times 10^{18}}$ mg CO/year-cm² earth surface = 0.04 mg/cm² year. Dividing this into the inventory of 0.1 mg/cm² we get $\gamma = 2.5$ years.

From the value of the specific activity obtained by us, and again assuming a CO concentration of 0.1 ppm, we can use the formulae given in our papers to obtain an independent value of This turns out to be much smaller, $\mathfrak{T} \approx 4 \times 10^{-2}$ years. However, this value is certainly low because the CO concentration of the air from which the CO was collected is much higher than 0.1 ppm. It is in the range 0.3 - 1 ppm and might be even higher. If would accordingly be 0.1 - 0.4 years, or possibly higher. I have no explanation for the remaining discrepancy - there could be a number of reasons for this.

I hope that this may be of some use to you.

Sincerely yours,

Richard Wolfgang
