-BEBLY FORM-ORIG. RETAINED New York, N.Y. 10021 (212) 002-0001 The Rockefeller Unit **JOSHOA LEDERBERG** Memo/Reply From

e. How to detect topological symmetry

f. How to compute degree of unsaturation from empirical formula

g. How to draw reasonable planar projections of molecular structures

h. How to generate all isomers including fused rings, spiro forms, etc.

i. How to generate all stereoisomers

i. How to find cycles and arbitrarily complex subgraphs

k. How to find the greatest common subgraph among a set of graphs

How to label nodes and edges of graphs in all distinct ways, taking account of symmetry

m. How to simulate specific chemical transformations, such as synthetic reactions

2. Knowledge of chemical stability

a. Twenty classes of unstable acyclic structures known; any others can be specified

b. How to recognize keto-enol fautomerism; other tautomers can be specified

c. Terpene rule

d. Isoprene rule

e. Bredt's rule

3. Knowledge of mass spectrometry

a. How to infer the formula of any molecular ion

b. How to compute results of any specified fragmentation and rearrangement

c. How to predict metastable peaks and use them for confirmation of inferences

d. Rule of charge placement on fragments (but not on atoms)

e. Half-order theory produces rough prediction of actual spectra

f. Refined theory can be added for any family of structures (now available for ketones, ethers, alcohols, amines, thiols, thioethers, estrogenic steroids, ketoandrostanes, marine sterols, and aromatic acids)

g. McLafferty rearrangement, water elimination, carbon monoxide elimination, carbon dioxide elimination, and elimination of other user defined "neutral species"

h Distinguishes high- and low-resolution spectra-

i. Distinguishes low voltage and high voltage measurements

4. Knowledge not available to DENDRAL

a. Three-dimensional structure (except of stereoisomerism)

b. Polymeric structures

c. Quantum mechanical explanations of mass spectrometry processes

d. Electronegativity

e. Physical properties such as dipole moment, molecular susceptibility, melting point, crystal structure, and many others

In addition, all the knowledge of LISP is presupposed by the DENDRAL programs. For example, arithmetic and set theoretic operations, symbol manipulation, interpretation of complex procedures, and countless bookkeeping operations. Considerable amounts of code are devoted to keeping track of intermediate results in the overall processing. This "specialized bookkeeping" knowledge is not very profound, yet it is indispensable for the integration of many complex procedures.

SUMMARY AND CONCLESIONS 159

Almost all DENDRAL's knowledge is tailored to the task of molecular structure elicidation. In spite of the eleganice and simplicity of compiting concepts we have to work with, the problem-solving procedures in DENDRAL are still very special purpose, complex, and voluminous. Making the procedures, and knowledge base, more general would have increased the burden of debugging them in most cases?

9.2.2 How Is Knowledge Employed in Heuristic DENDRAL and Meta-DENDRAL?

In Chapter 3 we described the organization of problem-solving systems. The major bifurcation was between algorithms and heuristic programs. Heuristic programs were further characterized as either search through a space of subproblems or as generation of candidates from a space of potential solutions. It is also possible that a problem space consists of partial solutions, as in the HI ARSAY speech-understanding system, [Firman and Tesser (1978), among others]. A space of partial solutions is in effect a combination of a space of solutions and a space of subproblems.

In either case, search or generation, the alternatives considered may be limited to those known to be legal according to a given rule, or to those that are merely plausible. In each case, problem solving may terminate with the discovery of a satisfactory solution, or proceed until the optimal solution is found.

To this initial division of heuristic programs, we added the concept of planning as exemplified by the planning phase of DFNDRAL's basic solution generation method. More generally, the use of planning can lead to computational economies in two ways. Planning can printe the space (of subproblems or solutions) by eliminating sections of it and directing search to certain other sections, or it can guide the problem solving, either by ordering the search generation sequence, or by modifying one subproblem/solution candidate to produce the next, using a hill-climbing (evolutionary) method, in the hybrid case of a space of partial solutions, both pruning and guidance methods are applicable.

Planning, furthermore, may be characterized along a different dimension. It may be data driven or expectation-driven. Data-driven planning begins by examination of data ffrom instruments, perhaps) and aftempts to induce hypotheses to account for it. Expectation-driven planning begins with a model of the phenomenon and uses it to establish expectations.

It is possible to establish a taxonomy of problem-solving systems based on these tour binary characteristics. (1) subproblem space versus solution space, (2) legal versus plausible alternatives considered, (3) pruning heuristics versus guidance heuristics, and (4) data driven versus expectation-driven. While such a taxonomy is useful, it should be remembered that the values of these dimensions are not mutually exclusive nor exhaustive, and indeed greater power will probably derive from future systems that combine these methods in various ways.

Hemistic DENDRAL may be characterized as a generator of legal solutions with

Many Jan Remarks

The state of the s

Their these reasons, we look forward to advances in automatic programming that will simplify the programming debuccing, and interfacing of complex procedures.
