2-Chloro-4-aminobenzoic acid
Inhibition and resistance mutations

Dec. 15, 1947.

Prepare plates of T(0) agar with 25 mg% CAB. Do. (0) agar.

Spread ca 10^2 cells of K-12 on both, incubate 72 hrs.

A) T(o) agar: 400 colonies noted

b) CAB: ca. 42 colonies noted. However, direct microscopic observation and smear impressions show a large number of "micro-colonies", probably equivalent to the difference between CAB and T(0) plates. Each colony contains, as a guess $10^4 - 10^5$ cells.

(This suggests that Strandskov's observations can be accounted for on the basis of spontaneous mutation and selection among the relatively large numbers of cells in the micro-colonies.)

Dec. 16, 1947.

Harvest from YP and cross W-55 x W-54, heterozygous for Lac₁, Mal, Sal, B₁ as well as V₁^R. Cross on EMS-maltose with .002% glucose added. +B₁.

A20. a) Estimate frequency of maltose⁻, and of sectored colonies. Score only those where the sectors could be scored accurately.

Proportion of Mal⁻ (including sectors). Count sectors as 1⁺ and 1⁻.

| 25 | 28 | 2 | | |

37. 47 3 73 160
 [23.2] [29.4] [1.9] [45.7]

$\chi^2 = .85$ $p = .6$

Compare with Table 5 of Kimber's paper.
 Retids were.

Is this medium's better? no

Mal must be between M and B. (no interaction with Lac).

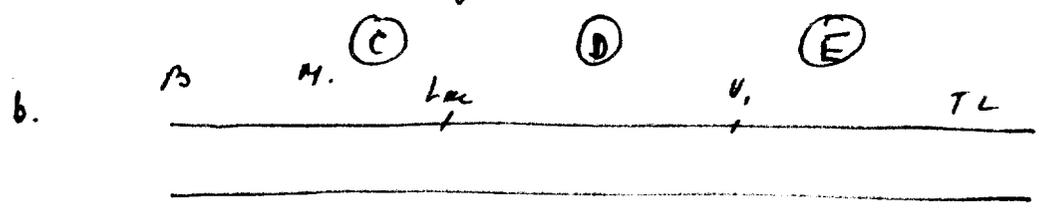

Compare with sectored colonies:

| | | | | | |
|----------|----|----|---|----|------|
| Intact. | 37 | 47 | 3 | 73 | 160. |
| Sectored | 44 | 43 | 1 | 42 | 90. |

Note: Absence of -R and deficiency of +S.

a) a double crossover in B₂L region does not interfere with chiasmata to the right - homogeneity of H₂L⁺ / H₂L⁻.

if a double takes place, it tends to be both in region D or, ^{both} in region (C). Very few doubles are recovered involving region E.

Killing curve.

Ded. 24, 1947.

Spread .1 ml. young (ca. 10^9) 58-161 culture on EMB-Lac plates.
Irradiate at 25 cm.

Lamp borrowed from Stauffer. operated in horizontal position, with 10 mins. warm-up allowed. This lamp has section of glass cut out to allow unfiltered uv radiation.

| Time | Surv. |
|-------|---|
| 5s | 37L + 33S = 70. ca. 10^4 ✓ |
| * 10s | ca 100L + do.S. 200. ✓ |
| * 15s | 52L + ca 100S = 130. Including 1 <u>white colony</u> . Streaks out + test with T1 |
| 20s | 17L + 26S = 43 |
| 30s | 13L + 9S = 22 |

Are these curves really non-linear? What about resistance of residuals?

Large and small colonies noted. Restreaks for mls. determination.

* Keyit as probable contaminant: not lysed by T1.

The difference between large and small colony noted on the above survival plates breeds true on the first restreaking on EMB-Lac. Transfer to slants as 67-1 and 67-2 for the large and small respectively.

Dec. 25, 1947.

Use same cells of 58-161 as in Exp. 67. Expose .1 ml culture per plate to 15 secs. UV from GE AH-4 lamp, as in 67. *EMB - Trehalose plates*

A). 9 plates.

Most plates, due to faulty pouring, had pitted surfaces and were very unsuitable for scoring. 1 plate, prepared earlier was more satisfactory. This had many (5-10%) colonies which had radial striae suggesting numerous variations affecting intensity of fermentation. Hold plate in refrigerator for later testing.

1/3/47. No mutants found.

Dec. 25, 1947.

Set up as in 68. EMB Mal plates.

Ca. 11 x 200 or 2200 colonies. 1 sector noted. Pick to slant as 69-1 for
later verification. =

large and small colony types seen as above.

Jan 2/48

all Malx.

Streakout on EMB ~~Mal~~ Mal

No mutants

Dec 27 1947.

Grow W-55 (58-161 Salicin pos. mutat,) in YP broth, harvest and conc. to ca. 10^{10} /ml. Irradiate 3 ml. in quartz flask ca 5 secs. rotating at front of Hanovia UV lamp, and inoc. .5 ml samples into 50 ml T(m) with .05% sugar.

1. Unirr.

- | | |
|-------------------|-----|
| A. Salicin (.1%) | 3+ |
| B. Cellobiose | - |
| C. b-Me Glucoside | 3+/ |
| | |
| 2. B. Cellobiose | - |
| C. b-Me-Glucoside | 3+ |

Incubate 37°

Examine Jan 3 48.

Streak out the b-MeGl cultures on similar ~~low~~ EMB plates. This may be slow rather than mutative utilization, as has been observed before.

No rapid utilization indicated on EMB - b-me glucoside plates. Growth assumed to be due to slow continuous utilization.

Raffinose tests continued from previous experiments; some possible diversity in progeny of repeated selections. Compare streaking of a - and ± colony.

A8. (3 da.) + types are somewhat more purplish than -. Buds true on this streaking and all colonies are more or less scoreable. Inoc. into .15% T(m) - Raffinose to continue selection. No growth.

A15. 1B (Cellobiose) noted to have reached +± while 2B is still ±. Streak out on EMB Cellobiose agar to isolate possible mutant.

A13 inoc melibiose TP (BM) : 58-161 to select more rapid Heli+ types. Streak out and compare with standard.

Jan 4 1948

OK. W-1 x

Jan. 5, 1958

Irradiate Y-53 on Tre-FMB plates, 10 sec. under Hanovia UV lamp.
10 plates.

10 x ca 150 = 1500 colonies.

2 colonies showed fairly distinct sectoring.

Retreated.

① and ② both give two colony types:

a.  Extensive darkening; no stem W-89 and W-~~89~~ 91

b.  central spot only. (This may be due to hydrolysis.)

W-90 W-92

2. colonies showed radial striation suggesting quantitative variations.
This is correlated with green sheen and from 1 colony, sheen+
and sheen- colonies noted. The original population is very
variable in this character.

Test on Maltose:

| | |
|----|----|
| 89 | ++ |
| 90 | ++ |
| 91 | ++ |
| 92 | ++ |

Retest on Tre EMB. (study Trehalose by filtration).

Jan 5, 1948.

3P. Inoc. Y105 into YP broth to obtain calls.

Lamp Broke Down

Use Stouffer's lamp. Irradiate 15 sec. (Y105 is apparently more sensitive to UV than is Y10)

Mal EMB 37 plates x ca 20 / plate. = 700 colonies. ~~No mutants~~

Lac EMB 38 x ca 20 = 750 colonies.

1 white colony noted. Struck out on Mal and Lac.

Mal - OK. Lac+ and morphologically identical with other types.

W-94.

Nutrition of W-93

Jan. 9 1947
