January 2nd 1957.

Dear Dr. Leiterberg

If you agree with me on the value (?) of the MS I sent to you I think that the next thing, for me, to do is to look into the fact that λ HFT (from a λ Gal⁻ transduced cell) does not multiply in a Gal⁻ cell. I would like to prove that λ HFT multiplies in a Gal⁺ cell and does not multiply as HFT in Gal⁻ cells, not picking the Gal⁻ marker of the host cell (I have preliminary experiments with a bad Gal⁻ of Cohnman bat seems to show that) or picking it and becoming a new HFT.

For these experiments I would need then your Gal⁻ and Gal⁺ strains sensitive to λ (I think the other markers don't matter unless you tell me why) and just in case Gal⁻, Gal⁺.

If I need to make them lysogenic I would prefer to have markers (+++) (according to Dale Kaiser) on the prophages.

So I would be very grateful to you if you could send me these three strains in Pasadena where I expect to be back in a week or so.

Thanks in advance

Yours

W.C. Jr.

P.S. Arber tells me that after transduction with HFT inactivated by UV most (if not all) of the transduced cells are stable Gal⁺ (and thus not heterogenotes). Did Morse find the same thing?
