Summary

There is no consistent pattern of uniform regional variations. Certain regions are more affected by specific diseases in a given year than others. In another year, there may be substantial changes.

While the war years have produced such changes, it has not been possible to establish any pattern of regional variation or wartime change.

THE REGIONAL INCIDENCE OF DISEASE IN GERMANY

I. INTRODUCTION

The diseases selected include diphtheria, scarlet fever, dysentery, typhoid, and paratyphoid, incidence rates of which are calculated per 10,000 inhabitants. Comparisons are presented for two pre-war years, 1938 and 1939, and two war years, 1941 and 1942.

More complete information pertaining to these diseases will be found in the relevant parts of Health in Axis Europe, R & A No. 1070, 6 October 1943. The present study concerns one aspect not treated there, the question of whether there is a consistent pattern of uniform regional variations in disease throughout the years. The war has changed the previous regional distribution of disease incidence but the changes have been of an erratic nature, precluding the formulation of general statements as to the evolution of a new pattern; nor has it been possible to ascertain the extent to which the findings presented in the following pages should be modified in the light of such factors as deficient reporting of diseases, recent population movements, or the effects of air raids. The scale on which population movements

occurred in 1942 is uncertain. It is also uncertain to what extent such movements are reflected in the population base of the rates and whether or not members of the armed forces are included.

The statistical data with respect to the incidence of the five diseases under study are presented in the tables on the following pages. The figures, which have been taken in their entirety from the Reichsgesundheitsblatt, the official publication of the Reich Health Office, are presented in two forms to illustrate different aspects of the problem.

There is first presented a series of 5 tables indicating the incidence of the respective diseases per 10,000 inhabitants in the various regions, in order to give a quantitative picture of the prevalence of disease.

Table 6, on the other hand, indicates the rank of the several regions of Germany according to the incidence of the diseases. The figures given are not of cases of disease, but show the rank of the given region among those of all Germany. Thus, Anhalt, which had the highest incidence of diphteria in 1938, is assigned the numeral "1" under that year; by 1939 it had fallen to ninth place, and is assigned the numeral "9". This table would reveal, should they exist, any fixed patterns in the regional incidence of the diseases under study.

II. INCIDENCE RATES OF SPECIFIC DISEASES

A. Diphtheria

The data do not reveal a consistent regional pattern. During the war years, Baden, Sachsen, the Sudeten territory, Bayern, and certain parts of Prussia show a rather high incidence. Of the regions, before the war, Bayern, Sachsen and Baden had a lower-than-average incidence. There is thus a possibility that the more recent outbreaks have been heavier in those regions which in former years were less exposed to this disease and thus had acquired a lesser degree of immunization. Table 1 on the following page indicates the number of cases of diphtheria per 10,000 inhabitants.

Table 1. CASES OF DIPHTHERIA PER 10,000 INHABITANTS

B. Scarlet Fever

Lippe, Bremen, Mecklenburg, Hamburg, Thüringen, Anhalt, the Sudeten territories, and some parts of Prussia show a high incidence of this disease throughout the years. The incidence is lower for the southern parts of Germany. Rates for Württemburg, Baden and Bavaria are consistently below the average. Table 2 on the following page indicates cases of scarlet fever per 10,000 inhabitants.

C. Dysentery

Hamburg, Mecklenburg, the Wartheland, and some parts of Prussia show a high incidence of this disease. The incidence is low in Württemberg, the Sudeten territory, the Saarland and Hessen. The range within which variations of this disease take place is wider than in the case of diphtheria and scarlet fever and extends from .11 per 10,000 to 4.7 per 10,000. Table 3 on the following page indicates the number of cases of dysentery per 10,000 inhabitants.

D. Typhoid Fever

This disease, which has increased greatly in recent years, occurs more widely in northern Germany than in the South. Regions showing a consistently high incidence include the Warthe-land, Danzig and Western Prussia, Mecklenburg and certain other parts of Prussia. The incidence is low in Baden, Bayern, Thüringen and the Saarland. Table 4 on the following page indicates the number of cases of typhoid fever per 10,000 inhabitants.

E. Paratyphoid Fever

Paratyphoid incidence is high in Austria, Oldenburg, Bremen, Mecklenburg and Hamburg. It is low in the Wartheland, Danzig and Western Prussia and Thüringen. Table 5 on the following page indicates the number of cases of paratyphoid fever per 10,000 inhabitants.

III. THE RANK OF THE REGIONS OF GERMANY
ACCORDING TO THE INCIDENCE OF SPECIFIC DISEASES

From the data given in the preceding tables, it is possible to construct a table showing the pattern of the incidence of the five diseases in the various regions of the country. Table 6 on the following page presents this information. In the table a numeral indicating rank among all the regions is assigned to each region for each of the four years, the region of highest incidence being indicated by "1", the next highest by "2", and so on. It is thus possible to determine whether any part or parts of Germany have shown a uniformly high or low rank either with respect to one or more diseases or with respect to all diseases over time.

Study of the table fails to indicate any very consistent pattern of uniform regional variations.
